Abstract

The purpose of this paper is to empirically determine the effects of political instability on economic growth. Using the system-GMM estimator for linear dynamic panel data models on a sample covering up to 169 countries, and 5-year periods from 1960 to 2004, we find that higher degrees of political instability are associated with lower growth rates of GDP per capita. Regarding the channels of transmission, we find that political instability adversely affects growth by lowering the rates of productivity growth and, to a smaller degree, physical and human capital accumulation. Finally, economic freedom and ethnic homogeneity are beneficial to growth, while democracy may have a small negative effect.

Keywords: Economic growth, political instability, growth accounting, productivity.

JEL codes: O43, O47

* The authors wish to thank Luísa Benta for excellent research assistance.

** The views expressed in this paper are those of the authors and do not necessarily represent those of the Central Bank of Chile and the International Monetary Fund.

1. Introduction

Political instability is regarded by economists as a serious malaise harmful to economic performance. Political instability is likely to shorten policymakers' horizons leading to sub-optimal short term macroeconomic policies. It may also lead to a more frequent switch of policies, creating volatility and thus, negatively affecting macroeconomic performance. Considering its damaging repercussions on economic performance the extent at which political instability is pervasive across countries and time is quite surprising. Measuring political instability by *Cabinet Changes*, that is, the number of times in a year in which a new premier is named and/or 50% or more of the cabinet posts are occupied by new ministers, figures speak for themselves. In Africa, for instance, there was on average a cabinet change once every two years in the period 2000-2003. Though extremely high, this number is a major improvement relative to previous years when there were, on average, two cabinet changes every three years. While Africa is the most politically unstable region of the world, it is by no means alone; as similar trends are observed in other regions (see Figure 1).

The widespread phenomenon of political (and policy) instability in several countries across time and its negative effects on their economic performance has arisen the interest of several economists. As such, the profession produced an ample literature documenting the negative effects of political instability on a wide range of macroeconomic variables including, among others, GDP growth, private investment, and inflation. Alesina et al. (1996) use data on 113 countries from 1950 to 1982 to show that GDP growth is significantly lower in countries and time periods with a high propensity of government collapse. In a more recent paper, Jong-a-Pin (2009) also finds that higher degrees of political instability lead to lower economic growth.¹ As regards to private investment, Alesina and Perotti (1996) show that socio-political instability

¹ A dissenting view is presented by Campos and Nugent (2002), who find no evidence of a causal and negative long-run relation between political instability and economic growth. They only find evidence of a short-run effect.

generates an uncertain politico-economic environment, raising risks and reducing investment.² Political instability also leads to higher inflation as shown in Aisen and Veiga (2006). Quite interestingly, the mechanisms at work to explain inflation in their paper resemble those affecting economic growth; namely that political instability shortens the horizons of governments, disrupting long term economic policies conducive to a better economic performance.

This paper revisits the relationship between political instability and GDP growth. This is because we believe that, so far, the profession was unable to tackle some fundamental questions behind the negative relationship between political instability and GDP growth. What are the main transmission channels from political instability to economic growth? How quantitatively important are the effects of political instability on the main drivers of growth, namely, total factor productivity and physical and human capital accumulation? This paper addresses these important questions providing estimates from panel data regressions using system-GMM on a dataset of up to 169 countries for the period 1960 to 2004. Our results are strikingly conclusive: in line with results previously documented, political instability reduces GDP growth rates significantly. An additional cabinet change (a new premier is named and/or 50% of cabinet posts are occupied by new ministers) reduces the annual real GDP per capita growth rate by 2.39 percentage points. This reduction is mainly due to the negative effects of political instability on total factor productivity growth, which account for more than half of the effects on GDP growth. Political instability also affects growth through physical and human capital accumulation, with the former having a slightly larger effect than the latter. These results go a long way to clearly understand why political instability is harmful to economic growth. It suggests that countries need to address political instability, dealing with its root causes and attempting to mitigate its effects on the quality and sustainability of economic policies engendering economic growth.

² Perotti (1996) also finds that socio-political instability adversely affects growth and investment. For a theoretical model linking political instability and investment, see Rodrik (1991).

The paper continues as follows: section 2 describes the dataset and presents the empirical methodology, section 3 discusses the empirical results, and section 4 concludes the paper.

2. Data and the empirical model

Annual data on economic, political and institutional variables, from 1960 to 2004 were gathered for 209 countries, but missing values for several variables reduce the number of countries in the estimations to at most 169. The sources of economic data were the *Penn World Table Version 6.2* – PWT (Heston et al., 2006), the World Bank’s *World Development Indicators* (WDI) and *Global Development Network Growth Database* (GDN), and the International Monetary Fund’s *International Financial Statistics* (IFS). Political and institutional data were obtained from the *Cross National Time Series Data Archive* – CNTS (Databanks International, 2007), the *Polity IV Database* (Marshall and Jaggers, 2005), the *State Failure Task Force* database (SFTF), and Gwartney and Lawson (2007).

The hypothesis that political instability and other political and institutional variables affect economic growth is tested by estimating dynamic panel data models for GDP per capita growth (taken from the PWT) for consecutive, non-overlapping, 5-year periods, from 1960 to 2004.³ Our baseline model includes the following explanatory variables (all except *Initial GDP per capita* are averaged over each 5-year period):

- *Initial GDP per capita (log)* (PWT): log of real GDP per capita lagged by one 5-year period. A positive coefficient, smaller than 1, is expected, indicating the existence of conditional convergence among countries;
- *Investment (% GDP)* (PWT). A positive coefficient is expected, as greater investment shares have been shown to be positively related with economic growth (Mankiw et al., 1992);

³ The periods are: 1960-64, 1965-69, 1970-74, 1975-79, 1980-84, 1985-89, 1990-94, 1995-99, and 2000-04.

- *Primary school enrollment* (WDI). Greater enrollment ratios lead to greater human capital, which should be positively related to economic growth. A positive coefficient is expected;
- *Population growth* (PWT). All else remaining the same, greater population growth leads to lower GDP per capita growth. Thus, a negative coefficient is expected;
- *Trade openness* (PWT). Assuming that openness to international trade is beneficial to economic growth, a positive coefficient is expected.
- *Cabinet changes* (CNTS). Number of times in a year in which a new premier is named and/or 50% of the cabinet posts are occupied by new ministers. This variable is our main proxy of political instability. It is essentially an indicator of regime instability, which has been found to be associated with lower economic growth (Jong-a-Pin, 2009). A negative coefficient is expected, as greater political (regime) instability leads to greater uncertainty concerning future economic policies and, consequently, to lower economic growth.

In order to account for the effects of macroeconomic stability on economic growth, two additional variables will be added to the model:⁴

- *Inflation rate* (IFS).⁵ A negative coefficient is expected, as high inflation has been found to negatively affect growth. See, among others, Edison et al. (2002) and Elder (2004);
- *Government (%GDP)* (PWT). An excessively large government is expected to crowd out resources from the private sector and be harmful to economic growth. Thus, a negative coefficient is expected.

The extended model will also include the following institutional variables:⁶

⁴ Here, we follow Levine et al. (2000), who accounted for macroeconomic stability in a growth regression by including the inflation rate and the size of government.

⁵ In order to avoid heteroskedasticity problems resulting from the high variability of inflation rates, *Inflation* was defined as $\log(1+Inf/100)$

⁶ There is an extensive literature on the effects of institutions on economic growth. See, among others, Acemoglu et al. (2001), Acemoglu et al. (2003), de Hann (2007), Glaeser et al. (2004), and Mauro (1995).

- *Index of Economic Freedom* (Gwartney and Lawson, 2007). Higher indexes are associated with smaller governments (Area 1), stronger legal structure and security of property rights (Area 2), access to sound money (Area 3), greater freedom to exchange with foreigners (Area 4), and more flexible regulations of credit, labor, and business (Area 5). Since all of these are favorable to economic growth, a positive coefficient is expected;
- *Ethnic Homogeneity Index* (SFTF): ranges from 0 to 1, with higher values indicating ethnic homogeneity, and equals the sum of the squared population fractions of the seven largest ethnic groups in a country. For each period, it takes the value of the index in the beginning of the respective decade. According to Easterly, et al. (2006), “social cohesion” determines the quality of institutions, which has important impacts on whether pro-growth policies are implemented or not. Since higher ethnic homogeneity implies greater social cohesion, which should result in good institutions and pro-growth policies, a positive coefficient is expected.⁷
- *Polity Scale* (Polity IV): from strongly autocratic (-10) to strongly democratic (10). This variable is our proxy for democracy. According to Barro (1996) and Tavares and Wacziarg (2001), a negative coefficient is expected.⁸

Descriptive statistics of the variables included in the tables of results are shown in Table 1.

-- Insert Table 1 about here --

The empirical model for economic growth can be summarized as follows:

$$\ln Y_{it} - \ln Y_{i,t-1} = \gamma \ln Y_{i,t-1} + \beta' \mathbf{X}_{it} + \delta PI_{i,t} + \lambda' \mathbf{W}_{it} + v_i + \mu_t + \varepsilon_{it}$$

$$i = 1, \dots, N \quad t = 1, \dots, T_i \quad (1)$$

where Y_{it} stands for the GDP per capita of country i at the end of period t , \mathbf{X}_{it} for a vector of economic determinants of economic growth, PI_{it} for a proxy of political instability, and \mathbf{W}_{it} for a vector of political and institutional determinants of economic growth; α , β , δ , and λ are the

⁷ See Benhabib and Rusticini (1996) for a theoretical model relating social conflict and growth.

⁸ On the relationship between democracy and growth, see also Acemoglu, et al. (2008).

parameters and vectors of parameters to be estimated, v_i are country-specific effects, μ_t are period specific effects, and, ε_{it} is the error term. With $\alpha = 1 + \gamma$, equation (1) becomes:

$$\ln Y_{it} = \alpha \ln Y_{i,t-1} + \beta' \mathbf{X}_{it} + \delta PI_{i,t} + \lambda' \mathbf{W}_{it} + v_i + \mu_t + \varepsilon_{it}$$

$$i = 1, \dots, N \quad t = 1, \dots, T_i \quad (2)$$

One problem of estimating this dynamic model using OLS is that $Y_{i,t-1}$ (the lagged dependent variable) is endogenous to the fixed effects (v_i), which gives rise to “dynamic panel bias”. Thus, OLS estimates of this baseline model will be inconsistent, even in the fixed or random effects settings, because $Y_{i,t-1}$ would be correlated with the error term, ε_{it} , even if the latter is not serially correlated.⁹ If the number of time periods available (T) were large, the bias would become very small and the problem would disappear. But, since our sample has only 9 non-overlapping 5-year periods, the bias may still be important.¹⁰ First-differencing Equation (2) removes the individual effects (v_i) and thus eliminates a potential source of bias:

$$\Delta Y_{it} = \alpha \Delta Y_{i,t-1} + \beta' \Delta \mathbf{X}_{it} + \delta \Delta PI_{i,t} + \lambda' \Delta \mathbf{W}_{it} + \Delta \mu_t + \Delta \varepsilon_{it}$$

$$i = 1, \dots, N \quad t = 1, \dots, T_i \quad (3)$$

But, when variables that are not strictly exogenous are first-differenced, they become endogenous, since the first difference will be correlated with the error term. Following Holtz-Eakin, Newey and Rosen (1988), Arellano and Bond (1991) developed a Generalized Method of Moments (GMM) estimator for linear dynamic panel data models that solves this problem by instrumenting the differenced predetermined and endogenous variables with their available lags in levels: levels of the dependent and endogenous variables, lagged two or more periods; levels of

⁹ See Arellano and Bond (1991) and Baltagi (2008).

¹⁰ According to the simulations performed by Judson and Owen (1999), there is still a bias of 20% in the coefficient of interest for $T=30$.

the pre-determined variables, lagged one or more periods. The exogenous variables can be used as their own instruments.

A problem of this difference-GMM estimator is that lagged levels are weak instruments for first-differences if the series are very persistent (see Blundell and Bond, 1998). According to Arellano and Bover (1995), efficiency can be increased by adding the original equation in levels to the system, that is, by using the system-GMM estimator. If the first-differences of an explanatory variable are not correlated with the individual effects, lagged values of the first-differences can be used as instruments in the equation in levels. Lagged differences of the dependent variable may also be valid instruments for the levels equations.

The estimation of growth models using the difference-GMM estimator for linear panel data was introduced by Caselli et al. (1996). Then, Levine et al. (2000) used the system-GMM estimator¹¹, which is now common practice in the literature (see Durlauf, et al., 2005, and Beck, 2008). Although several period lengths have been used, most studies work with non-overlapping 5-year periods.

3. Empirical Results

The empirical analysis is divided into two parts. First, we test the hypothesis that political instability has negative effects on economic growth, by estimating regressions for GDP per capita growth. As described above, the effects of institutional variables will also be analyzed. Then, the second part of the empirical analysis studies the channels of transmission. Concretely, we test the hypothesis that political instability adversely affects output growth by reducing the rates of productivity growth and of physical and human capital accumulation.

¹¹ For a detailed discussion on the conditions under which GMM is suitable for estimating growth regressions, see Bond et al. (2001).

3.1. Political Instability and Economic Growth

The results of system-GMM estimations on real GDP per capita growth using a sample comprising 169 countries, and 9 consecutive and non-overlapping 5-year periods from 1960 to 2004, are shown in Table 2. Since low economic growth may increase government instability (Alesina et al., 1996), our proxy for political instability, *Cabinet changes*, will be treated as endogenous. In fact, most of the other explanatory variables can also be affected by economic growth. Thus, it is more appropriate to treat all right-hand side variables as endogenous.¹²

The results of the estimation of the baseline model are presented in column 1. The hypothesis that political instability negatively affects economic growth receives clear empirical support. *Cabinet Changes* is highly statistically significant and has the expected negative sign. The estimated coefficient implies that when there is an additional cabinet change per year, the annual growth rate decreases by 2.39 percentage points. Most of the results regarding the other explanatory variables also conform to our expectations. *Initial GDP per capita* has a negative coefficient, which is consistent with conditional income convergence across countries. Investment and enrollment ratios¹³ have positive and statistically significant coefficients, indicating that greater investment and education promote growth. Finally, population growth has the expected negative coefficient, and *Trade (% GDP)* has the expected sign, but is not statistically significant.

-- Insert Table 2 about here --

The results of an extended model which includes proxies for macroeconomic stability are reported in column 2 of Table 2. Most of the results are similar to those of column 1. The main

¹² Their twice lagged values were used as instruments in the first-differenced equations and their once-lagged first-differences were used in the levels equation.

¹³ The results are virtually the same when secondary enrollment is used instead of primary enrollment. Since we have more observations for the latter, we opted to include it in the estimations reported in this paper.

difference is that *Trade (% GDP)* is now statistically significant, which is consistent with a positive effect of trade openness on growth. Regarding macroeconomic stability, inflation and government size have the expected signs, but only the first is statistically significant.

The *Index of Economic Freedom*¹⁴ is included in the model of column 3 in order to account for favorable economic institutions. It is statistically significant and has a positive sign, as expected. A one-point increase in that index increases annual economic growth by one percentage point. *Trade (% GDP)* and *Inflation* are no longer statistically significant. This is not surprising because the *Index of Economic Freedom* is composed of five areas, some of which are related to explanatory variables included in the model: size of government (Area 1), access to sound money (Area 3), and greater freedom to exchange with foreigners (Area 4). In order to avoid potential collinearity problems, the variables *Trade (% GDP)*, *Inflation*, and *Government (% GDP)* are not included in the estimation of column 4. The results regarding the *Index of Economic Freedom* and *Cabinet Changes* remain essentially the same.

An efficient legal structure and secure property rights have been emphasized in the literature as crucial factors for encouraging investment and growth (Glaeser, et al., 2004; Hall and Jones, 1999; La-Porta, et al., 1997). The results shown in column 5, where the *Index of Economic Freedom* is replaced by its *Area 2, Legal structure and security of property rights*, are consistent with the findings of previous studies.¹⁵

In the estimations whose results are reported in Table 3, we also account for the effects of democracy and social cohesion, by including the *Polity Scale* and the *Ethnic Homogeneity Index* in the model. There is weak evidence that democracy has small adverse effects on growth, as the

¹⁴ Since data for the *Index of Economic Freedom* is available only from 1970 onwards, the sample is restricted to 1970 to 2004 when this variable is included in the model.

¹⁵ Since *Investment (%GDP)* is included as an explanatory variable, the *Area 2* will also affect GDP growth through it. Thus, the coefficient reported for *Area 2* should be interpreted as the direct effect on growth, when controlling for the indirect effect through investment. This direct effect could operate through channels such as total factor productivity and human capital accumulation.

Polity Scale has a negative coefficient, small in absolute value, which is statistically significant only in the estimations of columns 1 and 3. These results are consistent with those of Barro (1996) and Tavares and Wacziarg (2001). As expected, higher ethnic homogeneity (social cohesion) is favorable to economic growth, although the index is not statistically significant in column 4. The results regarding the effects of political instability, economic freedom, and security of property rights are similar to those found in the estimations of Table 2. The most important conclusion that we can withdraw from these results is that the evidence regarding the negative effects of political instability on growth are robust to the inclusion of institutional variables.

-- Insert Table 3 about here --

Considering that political instability is a multi-dimensional phenomenon, eventually not well captured by just one variable (*Cabinet Changes*), we constructed five alternative indexes of political instability by applying principal components analysis.¹⁶ The first three indexes include variables that are associated with regime instability, the fourth has violence indicators, and the fifth combines regime instability and violence indicators. The variables (all from the CNTS) used to define each index were:

- *Regime Instability Index 1*: Cabinet Changes and Executive Changes.
- *Regime Instability Index 2*: Cabinet Changes, Constitutional Changes, Coups, Executive Changes, and Government Crises.
- *Regime Instability Index 3*: Cabinet Changes, Constitutional Changes, Coups, Executive Changes, Government Crises, Number of Legislative Elections, and Fragmentation Index.

¹⁶ This technique for data reduction describes linear combinations of the variables that contain most of the information. It analyses the correlation matrix, and the variables are standardized to have mean zero and standard deviation of 1 at the outset. Then, for each of the five groups of variables, the first component identified, the linear combination with greater explanatory power, was used as the political instability index.

- *Violence Index*: Assassinations, Coups, and Revolutions.
- *Political Instability Index*: Assassinations, Cabinet Changes, Constitutional Changes, Coups, and Revolutions.

The results of the estimation of the model of column 1 of Table 3 using the above-described indexes are reported in Table 4. While all indexes have the expected negative signs, the *Violence Index* is not statistically significant.¹⁷ Thus, we conclude that it is regime instability that more adversely affects economic growth. Jong-a-Pin (2009) and Klomp and de Haan (2009) reach a similar conclusion.

-- Insert Table 4 about here --

Several robustness tests were performed in order to check if the empirical support found for the adverse effects of political instability on economic growth remains when using restricted samples or alternative period lengths. Table 5 reports the estimated coefficients and t-statistics obtained for the proxies of political instability when the models of column 1 of Table 3 (for *Cabinet Changes*) and of columns 1 to 3 of Table 4 (for the three regime instability indexes) are estimated using seven alternative restricted samples.¹⁸ The first restricted sample (column 1 of Table 5) includes only developing countries, and the next four (columns 2 to 5) exclude one continent at a time.¹⁹ Finally, in the estimation of column 6, data for the 1960s and the 1970s is excluded from the sample, while in column 7 the last 5-year period (2000-2004) is excluded. Since *Cabinet Changes* and the three regime instability indexes are always statistically significant, we conclude that the negative effects of political instability on real GDP per capita growth are robust to sample restrictions.

¹⁷ The results for these 5 indexes are essentially the same when we include them in other models of Table 3 or in the models of Table 2. The same is true for indexes constructed using alternative combinations of the CNTS variables. These results are not shown here, but are available from the authors upon request.

¹⁸ The complete results of the 28 estimations of Table 5 and of the 16 estimations of Table 6 are available from the authors upon request.

¹⁹ The proxies of political instability were interacted with regional dummy variables in order to test for regional differences in the effects of political instability on growth. No evidence of such differences was found.

-- Insert Table 5 about here --

The results of robustness tests for alternative period lengths are reported in Table 6. The models of column 1 of Table 3 (for *Cabinet Changes*) and of columns 1 to 3 of Table 4 (for the three regime instability indexes) were estimated using consecutive, non-overlapping periods of 4, 6, 8 and 10 years. Again, all estimated coefficients are statistically significant, with a negative sign, providing further empirical support for the hypothesis that political instability adversely affects economic growth.

-- Insert Table 6 about here --

3.2. Channels of transmission

In this section, we study the channels through which political instability affects economic growth. Since political instability is associated with greater uncertainty regarding future economic policy, it is likely to adversely affect investment and, consequently, physical capital accumulation. In fact, several studies have identified a negative relation between political instability and investment (Alesina and Perotti, 1996; Mauro, 1985; Özler and Rodrik, 1992; Perotti, 1996). Instead of estimating an investment equation, we will construct the series on the stock of physical capital, using the perpetual inventory method, and estimate equations for the growth of the capital stock. That is, we will analyze the effects of political instability and institutions on physical capital accumulation.

It is also possible that political instability adversely affects productivity. By increasing uncertainty about the future, it may lead to less efficient resource allocation. Additionally, it may reduce research and development efforts by firms and governments, leading to slower technological progress. Violence, civil unrest, and strikes, can also interfere with the normal operation of firms and markets, reduce hours worked, and even lead to the destruction of some

installed productive capacity. Thus, we hypothesize that higher political instability is associated with lower productivity growth. Finally, human capital accumulation may also be adversely affected by political instability because uncertainty about the future may induce people to invest less in education.

Construction of the series

The series were constructed following the Hall and Jones (1999) approach to the decomposition of output. They assume that output, Y , is produced according to the following production function:

$$Y = K^\alpha (AH)^{1-\alpha} \quad (4)$$

where K denotes the stock of physical capital, A is a labor-augmenting measure of productivity, and H is the amount of human capital-augmented labor used in production. Finally, the factor share α is assumed to be constant across countries and equal to 1/3.

The series on the stock of physical capital, K , were constructed using the perpetual inventory equation:

$$K_t = I_t + (1 - \delta)K_{t-1} \quad (5)$$

where I_t is real aggregate investment in PPP at time t , and δ is the depreciation rate (assumed to be 6%). Following standard practice, the initial capital stock, K_0 , is given by:

$$K_0 = \frac{I_0}{g + \delta} \quad (6)$$

where I_0 is the value of investment in 1950 (or in the first year available, if after 1950), and g is the average geometric growth rate for the investment series between 1950 and 1960 (or during the first 10 years of available data).

The amount of human capital-augmented labor used in production, H_i , is given by:

$$H_i = e^{\varphi(s_i)} L_i \quad (7)$$

where s_i is average years of schooling in the population over 25 years old (taken from the most recent update of Barro and Lee, 2001), and the function $\varphi(s_i)$ is piecewise linear with slope 0.134 for $s_i \leq 4$, 0.101 for $4 < s_i \leq 8$, and 0.068 for $s_i > 8$. L_i is the number of workers (labor force in use).

With data on output, the physical capital stock, human capital-augmented labor used, and the factor share, the series of total factor productivity (TFP), A_i , can be easily constructed using the production function (4).²⁰ As in Hsieh and Klenow (2010), after dividing equation (4) by population N , and rearranging, we get a conventional expression for growth accounting.

$$\frac{Y}{N} = \left(\frac{K}{N}\right)^\alpha \left(A \frac{H}{N}\right)^{1-\alpha} \quad (8)$$

This can also be expressed as:

$$y = k^\alpha (Ah)^{1-\alpha} \quad (9)$$

where y is real GDP per capita, k denotes the stock of physical capital per capita, A is TFP, and h is the amount of human capital per capita.

The individual contributions to GDP per capita growth from physical and human capital accumulation and TFP growth can be computed by expressing equation (9) in rates of growth:

$$\Delta y = \alpha \Delta k + (1 - \alpha) \Delta A + (1 - \alpha) \Delta h \quad (10)$$

²⁰ See Caselli (2005) for a more detailed explanation of how the series are constructed. We also follow this study in assuming that the depreciation rate of physical capital is 6 per cent and that the factor share α is equal to 1/3. The series of output, investment and labor are computed as follows (using data from the PWT 6.2): $Y = rgdpch*(pop*1000)$, $I = (ki/100)*rgdpl*(pop*1000)$, $L = rgdpch*(pop*1000)/rgdpwok$. Population is multiplied by 1000 because the variable pop of PWT 6.2 is scaled in thousands.

Empirical results

Table 7 reports the results of estimations in which the growth rate of physical capital per capita is the dependent variable,²¹ using a similar set of explanatory variables as for GDP per capita growth.²² Again, *Cabinet Changes* and the three regime instability indexes are always statistically significant, with a negative sign. Thus, we find strong support for the hypothesis that political instability adversely affects physical capital accumulation. Since the accumulation of capital is done through investment, our results are consistent with those of previous studies which find that political instability adversely affects investment (Alesina and Perotti, 1996; Özler and Rodrik, 1992). There is some evidence that economic freedom is favorable to capital accumulation (column 2), but democracy and ethnic homogeneity do not seem to significantly affect it.

-- Insert Table 7 about here --

The next step of the empirical analysis was to analyze another possible channel of transmission, productivity growth. The results reported in Table 8 provide clear empirical support for the hypothesis that political instability adversely affects productivity growth, as *Cabinet Changes* is always statistically significant, with a negative sign.²³ Economic freedom, which had positive effects on GDP growth, is also favorable to TFP growth. As can be seen in columns 4 to 6, we find clear evidence that regime instability adversely affects TFP growth. Thus, we can

²¹ A second lag of physical capital had to be included in the right hand-side in order to avoid second order autocorrelation of the residuals. Although the coefficient for the first lag is positive, the second lag has a negative coefficient, higher in absolute value. Thus, when we add up the two coefficients for the lags of physical capital, we get negative values whose magnitude is in line with those obtained for lagged GDP per capita in the previous tables.

²² Since the variable *Investment (%GDP)* – variable *ki* from the PWT 6.2 - was used to construct the series of the stock of physical capital, it was not included as an explanatory variable. Nevertheless, the results for political instability do not change when the investment ratio is included.

²³ Data on investment and human capital were used to construct the TFP series. Thus, the variables *Investment (%GDP)* and *Primary School Enrollment* were not included as explanatory variables in the estimations for TFP growth reported in Table 8. But, when they are included, the results for the other explanatory variables do not change significantly.

conclude that an additional channel through which political instability negatively affects GDP growth is productivity growth.

-- Insert Table 8 about here --

Finally, Table 9 reports the results obtained for human capital growth.²⁴ Again, *Cabinet Changes* and the regime instability indexes are always statistically significant, with the expected negative signs. Regarding the institutional variables, democracy seems to positively affect human capital growth, as the *Polity Scale* is statistically significant, with a positive sign, in columns 3 to 5. There is also weak evidence in column 4 that ethnic homogeneity is favorable to human capital accumulation. Finally, openness to trade has positive effects on human capital accumulation.

-- Insert Table 9 about here --

Effects of the three transmission channels

The last step of the empirical analysis was to compute the effects of political instability on GDP per capita growth through each of the three transmission channels, using equation (10). The results of this growth decomposition exercise are reported in Table 10, which shows, for each proxy of political instability, the estimated coefficients,²⁵ the effects on GDP per capita growth, and the percentage contributions to the total effects.

More than half of the total negative effects of political instability on real GDP per capita growth seem to operate through its adverse effects on total factor productivity (TFP) growth, as this channel is responsible for 52.13% to 58.40% of the total effects. Thus, according to our results, TFP growth is the main transmission channel through which political instability affects real GDP per capita growth. Regarding the other channels, physical capital accumulation

²⁴ Since data on education was used to construct the series of the stock of human capital, *Primary School Enrollment* was not included as an explanatory variable in the estimations of Table 9. If included, it is statistically significant, with a positive sign, and results regarding the effects of political instability remain practically unchanged.

²⁵ The coefficients for the proxies of political instability are those reported in columns 2 to 5 of Table 7 (Growth of Physical Capital per capita), Table 8 (Growth of TFP), and Table 9 (Growth of Human Capital per capita).

accounts for 22.59% to 28.71% of the total effect, while the growth of human capital accounts for 17.08% to 21.11%.

-- Insert Table 10 about here --

The total effects of political instability reported in the last column of Table 10 are somewhat smaller than those obtained for the proxies of political instability in the estimations of column 1 of Table 3 (for *Cabinet Changes*) and of columns 1 to 3 of Table 4 (for the three regime instability indexes).²⁶ These differences may be in part due to the fact that the number of observations and the set of explanatory variables are not always the same in all estimations.

4. Conclusions

This paper analyzes the effects of political instability on growth. In line with the literature, we find that political instability significantly reduces economic growth, both statistically and economically. But, we go beyond the current state of the literature by quantitatively determining the importance of the transmission channels of political instability to economic growth. Using a dataset covering up to 169 countries in the period between 1960 and 2004, estimates from system-GMM regressions show that political instability is particularly harmful through its adverse effects on total factor productivity growth and, in a lesser scale, by discouraging physical and human capital accumulation. By identifying and quantitatively determining the main channels of transmission from political instability to economic growth, this paper contributes to a better understanding on how politics affects economic performance.

²⁶ For example, the estimated coefficient for *Cabinet Changes* in column 1 of Table 3 is -0.0321, while the total effect of the three channels reported in the last column of Table 8 is -0.0288 (about 10% smaller). This small difference in both methods is to be expected due to the assumptions behind the decomposition method, namely, that α and δ are equal to 1/3 and 6 percent, respectively. In fact, the functional form of the production function is a strong assumption affecting calculations. Thus, given the different nature of the exercises, the differences between both methods should be regarded as small.

Our results suggest that governments in politically fragmented countries with high degrees of political instability need to address its root causes and try to mitigate its effects on the design and implementation of economic policies. Only then, countries could have durable economic policies that may engender higher economic growth.

- Notes: - System-GMM estimations for dynamic panel-data models. Sample period: 1960-2004;
- The dependent variable is the growth rate of real GDP per capita;
- Each coefficient shown comes from a separate regression. That is, this table summarizes the results of 28 estimations. The complete results are available from the authors upon request;
- The explanatory variables used, besides the proxy for political instability indicated in each row, are those of the model of column 1 of Table 3 (for Cabinet Changes) and columns 1 to 3 of Table 4 (for the regime instability indexes);
- All explanatory variables were treated as endogenous. Their lagged values two periods were used as instruments in the first-difference equations and their once lagged first-differences were used in the levels equation;
- Two-step results using robust standard errors corrected for finite samples (using Windmeijer's, 2005, correction).
- t-statistics are in parenthesis. Significance level at which the null hypothesis is rejected: ***, 1%; **, 5%, and *, 10%.

Table 10: Transmission Channels of Political Instability into GDP Growth

<i>Proxy of Political Instability</i>		Channels of Transmission			Total Effect of the 3 Channels on the Growth of GDPpc
		Growth of Physical Capital pc	Growth of TFP	Growth of Human Capital pc	
<i>Cabinet Changes</i>	Coefficient	-0.0195***	-0.0243*	-0.00911**	
	Effect on GDP	-0.0065	-0.0162	-0.0061	-0.0288
	% of Total Effect	22.59%	56.30%	21.11%	100%
<i>Regime Instability Index 1</i>	Coefficient	-0.0108**	-0.0129**	-0.00379**	
	Effect on GDP	-0.0036	-0.0086	-0.0025	-0.0147
	% of Total Effect	24.44%	58.40%	17.16%	100%
<i>Regime Instability Index 2</i>	Coefficient	-0.00932**	-0.00846*	-0.00311**	
	Effect on GDP	-0.0031	-0.0056	-0.0021	-0.0108
	% of Total Effect	28.71%	52.13%	19.16%	100%
<i>Regime Instability Index 3</i>	Coefficient	-0.00906**	-0.00964**	-0.00292*	
	Effect on GDP	-0.0030	-0.0064	-0.0019	-0.0114
	% of Total Effect	26.51%	56.41%	17.08%	100%

Sources: See Table 1

Notes: - The estimated coefficients were taken from: columns 2 to 5 of Table 7, for the Growth of Physical Capital per capita; columns 2 to 5 of Table 8, for the Growth of TFP; and, columns 2 to 5 of Table 9, for the Growth of Human Capital per capita.

- The effects of each channel on the growth of real GDP per capita are obtained by multiplying: the coefficient obtained for the growth of Physical Capital per capita by $\alpha=1/3$; the coefficient obtained for the growth of TFP by $(1-\alpha)=2/3$; and, the coefficient obtained for the growth of Human Capital per capita by $(1-\alpha)=2/3$. That is, we apply equation (10): $\Delta y = \alpha\Delta k + (1-\alpha)\Delta A + (1-\alpha)\Delta h$.
